Do you need your own OAuth app?

A lookup tool that tells a Composio developer, in about thirty seconds, whether they need their own OAuth app, how long approval really takes, and what they can start today.

What it is

Three hand-verified seed guides — GitHub, Google/Gmail and Meta/Facebook — chosen to cover three different blocker types: no review, scope review, and business verification. Anything else is researched live by an agent that reads the provider's own documentation and writes a guide in the same schema, streaming its progress. Generated guides persist, so their URLs are shareable. Slack, Zoom and Figma are agent-generated examples.

What's worth a closer look

Evidence is enforced in code, not prompting. Every factual statement is a claim with a status (tested / sourced / inferred / unverified), its sources, and the date checked. Citations are built from the list of pages the agent provably retrieved, so a URL that 404s cannot be cited. Generated guides are forbidden from claiming *tested*, and dangling claim references are rejected — anything failing goes back for one repair pass. When the Zoom run lost four of eight source pages, the gaps surfaced as open questions rather than confident prose.

Two things to know before you try it

- **It runs on Gemini, not the Anthropic API the brief specified.** It was built on Anthropic first, then switched: Anthropic has no free tier, and "no paid accounts" was the harder constraint. Google Search grounding also has no free quota, so the agent fetches documentation URLs directly instead of searching — which turned out to suit the problem better, since Gemini reports exactly which pages it retrieved.
- **Free-tier quota allows roughly 5–7 live generations per day.** If you hit a quota message, every existing guide still works — only new generation is affected.

Where the detail lives

`README.md` covers setup, the decisions behind the guide's ordering and evidence model, how the agent works, and its limits — including what is not built. `docs/verification.md` records what was checked against primary sources, two corrections it turned up (Google's own documentation puts the CASA assessment fee at $500–$4,500, not the ~$540–$3,000 a third-party source claimed, and a cited URL had gone dead), and what remains unverified.

Next.js (App Router) · TypeScript · Tailwind · Zod · Gemini · Upstash Redis · Vercel. To run locally: `npm install`, copy `.env.example` to `.env.local` and set `GEMINI_API_KEY` (free, no billing account), then `npm run dev`.
